Abstract

Traditional knowledge had been established to successfully preserve and restore biodiversity across the continent since it accommodates indigenous herbalism. Traditional medicine had been adopted in Nigeria prior to the colonialism era. The study examined the phytochemical constituents in methanolic seed extract of alligator pepper (Aframomum melegueta) grown in Nigeria by Fourier Transform Infrared Spectrophotometer (FT-IR) and High Performance Liquid Chromatography (HPLC) analyses. *Aframomum melegueta* seeds were extracted with 70% methanol at room temperature for 48 h. The functional groups in aqueous methanolic seed extract were determined using FT-IR spectroscopic method while the bioactive compounds were determined using HPLC. The FT-IR result established the presence of N-H, C=O, C-O and O-H functional groups in the methanolic extract. The HPLC analysis of the methanolic extract identified ten compounds. The major components were farnesyl (37.11%), lycopene (34.15%), dihydrocapsaicin (9.55%), capsaicin (8.40%) and delphenidin (7.91%). Other compounds present in the extract at lower levels were phytoene (0.74%), β-lonone (0.57%), limonene (0.56%), 6-methoxymellon (0.56%) and trans-beta-ocimene (0.45%). In essence, this study established the ethnobotanical use of *Aframomum melegueta* as functional food ingredient.

Keywords: *Aframomum melegueta*, phytochemical, FT-IR, HPLC

Introduction

Traditional medicine is globally accepted for health care. It is related to the knowledge and practice adopted in diagnosing, preventing, and treating disease to enhance general health and wellness. Traditional medicine has been used to treat common diseases since ancient times.¹ A medicinal plant is any plant which, in one or more of its organs, contains substances that can be used for the management of diseases or for the synthesis of drugs. Specifically, the medicinal value of these plants lies in some chemical substances that produce a definite physiological action in human or animal system.² The bioactive constituents are majorly the alkaloids, flavonoids, tannins and phenolic compounds.

*Aframomum melegueta* is a tropical herbaceous perennial plant of the genus *Aframomum* belonging to the family Zingiberaceae (ginger family) of the angiosperms in the Kingdom plantae. This plant has orange coloured lips and pinkish-orange upper flowers that can develop into fleshy indehiscent pods. The pods contain numerous small, reddish brown seeds.

This plant is also known as *alligator pepper*, *grains of paradise*, *guinea pepper* or *melegueta pepper*. It is native to tropical African countries such as Ghana, Nigeria, Sierra Leone, Liberia, Togo and Côte d’Ivoire.³ This traditional plant which is well known in Nigeria as "*Ataare*" has been used for years in the management of diseases. The advances in analytical techniques including High Performance Liquid Chromatography (HPLC) and Fourier Transform Infrared Spectrophotometer (FT-IR) are techniques for the identification and determination of phytochemical compounds. HPLC analytical technique is used for the isolation of various plant materials. It is a technique that can separate a mixture of compounds and identify, quantify and purify the individual components in a mixture. Over the years, this technique is gaining popularity for fingerprinting study for the quality control of herbal plants.¹ FT-IR is most recognized tool for identifying the types of chemical bonds (functional groups) present in compounds. The wavelengths of light absorbed characteristic the chemical bond presented in an annotated spectrum. The study determined the bioactive compounds present in methanol extract of *Aframomum melegueta* using HPLC and FT-IR techniques, which may provide an explicate to its use in folklore medicine.

Materials and Methods

Plant material

*Aframomum melegueta* pods containing the seeds were purchased from Oja Oba market in Iwo, Osun State, Nigeria. The seeds are identified...
using iNaturalist and authenticated by a taxonomist in the Biology Programme of the Bowen University.

**Plant sample**

The alligator pepper pods were shade dried for 7 days. After drying, the seeds were manually separated from pods and winnowed to remove adhering shafts. The seeds were ground with laboratory blender (MX-795N, National, Japan), screened through 70 mesh sieve and stored in sealed glass container prior to use. Plate 1 shows *Aframomum melegueta* pods, seeds and powder, respectively.

**Extraction procedure**

The ground sample (450g) was extracted with 2250 mL of 70% methanol. The mixture was shaken for 48 h using bath shaker at room temperature, filtered using Whatmans No. 1 filter paper and then preserved at 4 °C for further process.

**FT-IR spectroscopic analysis**

Crude extract of *Aframomum melegueta* was used for the FT-IR spectroscopic analysis. The crude extract was loaded in the crystal surface of FT-IR spectroscopic (Cary 630, Agilent Technologies), with a scan range from 650 to 4000 cm

**HPLC analysis**

The HPLC analysis of the methanolic crude extract was carried out using chromatographic system (Shimadzu, Nexera MX) with a UV detector. The data generated was recorded and processed using 3000 software.

**Results and Discussion**

**FT-IR spectrum of *Aframomum melegueta***

The identified functional groups in *Aframomum melegueta* methanolic seed extract (AMMSE) are as shown in Table 1. The spectrum as presented in Figure 1 identified the functional groups in the extract based on the peaks values represented in the region of infrared radiation. The FT-IR results established the presence of N-H, C=O, C=C, O-H functional groups. Over the years, FT-IR spectroscopy has proven to be sensitive and reliable for the detection of biomolecular composition.

The compounds present in the AMMSE identified by HPLC analytical technique are as presented in Figure 2. Research interest on the standardization and characterization of herbal drugs is ever increasing with the advent of modern chromatographic systems which offer rapid, convenient and cost effective analyses. Ten compounds were identified in the AMMSE using HPLC. The major components were farnesyl (37.11%), lycopene (34.15%), dihydrocapsaicin (9.55%), capsaicin (8.40%) and delphenidin (7.91%). Other compounds present in the extract at low levels were phytone (0.74%), β-lonone (0.57%), limonene (0.56%), 6-methoxymellonene (0.56%) and trans-beta-ocimene (0.45%).

The seed extract has highest concentration of farnesyl (37.11%) as indicated in Figure 2. A variety of eukaryotic proteins has the potential to undergo post-translational modification by the attachment of a farnesyl group to a cysteine residue. This process results in the formation of a thioether bond. Farnesylated proteins perform a variety of functions in cells such as enzyme catalysts, structural proteins and components in signal transduction networks. Most importantly, since constitutive activation of target protein such as Ras, is a major contributory factor in a number of alignment human tumors, its inactivation by interfering with the farneslylation step has been extensively studied as a strategy to develop new anticancer agents.

Asides, the extract also contain other colourless precursor carotenoid such as phytone though in much lower level (9.55%) compared to the lycopene. Phytone are linear hydrocarbons, more specifically they are alkenes with 9 double bonds. It has three of its double bonds conjugated (3c,d,b). However, it is considered that at least 7c,d,b are needed for a carotenoid to exhibit color; hence phytone with lower value is considered colorless carotenoid. Phytone are present in common Western diet such as tomato, grapefruits, watermelon etc and in some peppers and it is readily absorbed by humans. Animal models of carotenoid absorption even suggested preferential of phytone in some tissues. Most importantly, lacking color, this carotenoid precursor can be especially useful in food development where such attribute is not desired. There is evidence that lycopene or its metabolites could protect from light damage and oxidative stress, exhibit anti-inflammatory activity or exert anti carcinogenic activity.

Delphenidin is a purple coloured plant pigment that is highly active in its aglycone form. Several animal and human clinical studies have shown that delphenidin exerts beneficial effects on gut microbiota. Most importantly, increasing evidence shows its potential pharmaceutical and nutraceutical applications, as indicated by exhibiting the activities of anti-oxidation, anti-inflammation, anti-microorganism, anti-diabetes, cardiovascular protection and anti-cancer. β-lonone is a natural plant volatile compound, and it is the 9,10 and 9,10’ cleavage product of β-carotenoid by the carotenoid cleavage dioxygenase. It is widely distributed in flowers, fruits and vegetables and could also be endogenously produced. β-lonone, whether of an endogenous or exogenous origin, possesses anti cancer, anti inflammatory and anti microbial effects. Trans-beta-ocimene is one of the most common monoterpene found in nature. In the field of botanical medicine, there is an association of β-ocimene in essential oils with anticonvulsant activity, antifungal activity, antitumor activity and pest resistance.
Limonene is found in the essential oils of aromatic plants. The therapeutic effects of limonene have been extensively studied, proving anti-inflammatory, antioxidant, antinociceptive, anticancer, antidiabetic, antihyperalgesic, antiviral, and gastroprotective effects, among other beneficial effects in health. Pepper fruits and their products contain capsaicinoids responsible for the pungency. The two most abundant capsaicinoids in peppers are capsiacin and dihydrocapsaicin, both constituting about 90%, with capsiacin accounting for approximately 71% of the total capsaicinoids in most of the pungent pepper varieties. The AMMSE had 8.40% and 9.55% of capsiacin and dihydrocapsaicin, respectively. Capsiacin had been reported to possess analgesic, anticancer and anti-cardiovascular potentials. Plants possess various biochemical and structural defense mechanisms which protect them against infection such as 6-methoxymellin reported in AMMSE. The compound is a phytoalexin that is inhibitory to Botrytis cinerea and Sclerotinia sclerotiorum. It is however imperative to note that it has recently been demonstrated that phytoalexins may also display health-promoting effects in humans. For instance, resveratrol produced by Vitaceae has been reported as a cardioprotective, antitumor, neuroprotective and antioxidant agent as well as an antifungal and antibacterial.

Conclusion
The present work established the various phytochemicals and FT-IR parameters in methanolic seed extract of Aframomum melegueta which could be of interest in therapeutic applications in Nigeria. This primary information will facilitate studies on the safety and efficacy of the extract in clinical trials.
